Overview of Method

1. Use kernel conditional density estimation (KCDE) to obtain separate predictive distributions for incidence in each future week.
2. Use copulas to combine these individual distributions to get joint predictive distribution for the trajectory of incidence over the rest of the season.
3. Obtain predictive distributions for onset week, peak ILI, and peak week from this joint predictive distribution.
Article under review, draft pdf at http://tinyurl.com/j5o7uf7
More detail about KCDE

Viboud et al., Prediction of the spread of influenza epidemics by the method of analogues. American Journal of Epidemiology, 2003.

Motivation for Copulas

- ▶ We need to capture dependence in incidence across different horizons to get at things like onset timing, peak timing.

(Slightly) more detail about copulas

▶ Sklar's Theorem: For any random vector $(X_1, \ldots, X_D)$, there exists a function C such that
$$F_{X_1,\ldots,X_D}(x_1,\ldots,x_D) = C\{F_{X_1}(x_1),\ldots,F_{X_D}(x_d)\}$$

▶ We have used the parametric specification for C that arises in a multivariate normal distribution

Observed and Simulated Trajectories of Influenza-like Illness Incidence

Observed Trajectories by Season

Simulated Trajectories: KCDE with Copula

Simulated Trajectories: KCDE with Independence Across Horizons
A Weakness: The Christmas Effect

- Our method did not capture the Christmas effect:

"Christmas effect" in Influenza–like Illness Incidence
Future Directions

- ▶ Participate fully (all regions, consistent model formulation throughout)
- ▶ Ensembles to combine models with varying strength at different points in the season
    - ▶ (Unconditional) KDE near the beginning of the season?
    - ▶ SARIMA near Christmas?
    - ▶ KCDE+copulas elsewhere?
- ▶ We have some other ideas, but won't get to them by the start of the next round...
